

Authorization Types

Forms of authorization on parts of the database:

- Read allows reading, but not modification of data.
- Insert allows insertion of new data, but not modification of existing data.
- Update allows modification, but not deletion of data.
- Delete allows deletion of data.

Forms of authorization to modify the database schema

- Index allows creation and deletion of indices.
- **Resources** allows creation of new relations.
- Alteration allows addition or deletion of attributes in a relation.
- Drop allows deletion of relations.

Authorization Specification in SQL

- The grant statement is used to confer authorization grant <privilege list> on <relation name or view name> to <user list>
- <user list> is:
 - a user-id
 - public, which allows all valid users the privilege granted
 - A role (more on this later)
- Granting a privilege on a view does not imply granting any privileges on the underlying relations.
- The grantor of the privilege must already hold the privilege on the specified item (or be the database administrator).

Privileges in SQL

- select: allows read access to relation, or the ability to query using the view
 - Example: grant users U_1 , U_2 , and U_3 select authorization on the *instructor* relation:

grant select on instructor to U_1 , U_2 , U_3

- insert: the ability to insert tuples
- update: the ability to update using the SQL update statement
- delete: the ability to delete tuples.
- all privileges: used as a short form for all the allowable privileges

Revoking Authorization in SQL

- The **revoke** statement is used to revoke authorization.
 - revoke <privilege list>
 - **on** <relation name or view name> **from** <user list>
- Example:
 - revoke select on branch from U_1 , U_2 , U_3
- If <revokee-list> includes public, all users lose the privilege except those granted it explicitly.
- If the same privilege was granted twice to the same user by different grantees, the user may retain the privilege after the revocation by one grantee.
- All privileges that depend on the privilege being revoked are also revoked.

Roles

- create role instructor;
- **grant** instructor to Amit;
- Privileges can be granted to roles:
 - grant select on takes to instructor;
- Roles can be granted to users, as well as to other roles
 - create role teaching_assistant
 - grant teaching_assistant to instructor;
 - Instructor inherits all privileges of teaching_assistant
- Chain of roles
 - create role dean;
 - grant instructor to dean;
 - grant dean to Satoshi;

Authorization on Views

- create view geo_instructor as
 (select *
 from instructor
 where dept_name = 'Geology');
- grant select on geo_instructor to geo_staff
- Suppose that a geo_staff member issues
 - select * from geo_instructor;
- What if
 - geo_staff does not have permissions on instructor?
 - creator of view did not have some permissions on instructor?

Other Authorization Features

- references privilege to create foreign key
 - grant reference (dept_name) on department to Mariano;
 - why is this required?
- transfer of privileges
 - grant select on department to Amit with grant option;
 - revoke select on department from Amit, Satoshi cascade;
 - revoke select on department from Amit, Satoshi restrict;
- Etc. read Section 4.6 for more details we have omitted here.

More Advanced SQL (from chp 5)

- Accessing SQL From a Programming Language
 - Dynamic SQL
 - JDBC and ODBC
 - Embedded SQL
- SQL Data Types and Schemas
- Functions and Procedural Constructs
- Triggers
- Advanced Aggregation Features
- OLAP

JDBC and **ODBC**

- API (application-program interface) for a program to interact with a database server
- Application makes calls to
 - Connect with the database server
 - Send SQL commands to the database server
 - Fetch tuples of result one-by-one into program variables
- ODBC (Open Database Connectivity) works with C, C++, C#, and Visual Basic
- JDBC (Java Database Connectivity) works with Java
- HDBC-ODBC and others

JDBC

- JDBC is a Java API for communicating with database systems supporting SQL.
- JDBC supports a variety of features for querying and updating data, and for retrieving query results. Also for accessing metadata.
- JDBC also supports metadata retrieval, such as querying about relations present in the database and the names and types of relation attributes.
- Model for communicating with the database:
 - Open a connection
 - Create a "statement" object
 - Execute queries using the Statement object to send queries and fetch results
 - Exception mechanism to handle errors

ODBC

- Open DataBase Connectivity(ODBC) standard
 - standard for application program to communicate with a database server.
 - application program interface (API) to
 - open a connection with a database,
 - send queries and updates,
 - get back results.
- Applications such as GUI, spreadsheets, etc. can use ODBC
- Was defined originally for Basic and C, versions available for many languages.

Embedded SQL

- The SQL standard defines embeddings of SQL in a variety of programming languages such as C, Java, and Cobol.
- A language to which SQL queries are embedded is referred to as a host language, and the SQL structures permitted in the host language comprise embedded SQL.
- The basic form of these languages follows that of the System R embedding of SQL into PL/I.
- EXEC SQL statement is used to identify embedded SQL request to the preprocessor

EXEC SQL <embedded SQL statement > END_EXEC

Note: this varies by language (for example, the Java embedding uses # SQL { };)

Example Query

- From within a host language, find the ID and name of students who have completed more than the number of credits stored in variable credit_amount.
- Specify the query in SQL and declare a cursor for it

```
EXEC SQL
```

```
declare c cursor for
select ID, name
from student
where tot_cred > :credit_amount
END_EXEC
```

Embedded SQL (Cont.)

The open statement causes the query to be evaluated

EXEC SQL open c END_EXEC

The fetch statement causes the values of one tuple in the query result to be placed on host language variables.

EXEC SQL fetch c into :si, :sn END_EXEC

Repeated calls to **fetch** get successive tuples in the query result

- A variable called SQLSTATE in the SQL communication area (SQLCA) gets set to '02000' to indicate no more data is available
- The close statement causes the database system to delete the temporary relation that holds the result of the query.

EXEC SQL close c END_EXEC

Note: above details vary with language. For example, the Java embedding defines Java iterators to step through result tuples.

Updates Through Cursors

Can update tuples fetched by cursor by declaring that the cursor is for update

```
declare c cursor for
    select *
    from instructor
    where dept_name = 'Music'
for update
```

To update tuple at the current location of cursor c

```
update instructor
set salary = salary + 100
where current of c
```

Procedural Constructs in SQL

Procedural Extensions and Stored Procedures

- SQL provides a module language
 - Permits definition of procedures in SQL, with if-then-else statements, for and while loops, etc.
- Stored Procedures
 - Can store procedures in the database
 - then execute them using the call statement
 - permit external applications to operate on the database without knowing about internal details
- Object-oriented aspects of these features are covered in Chapter
 22 (Object Based Databases)

Triggers

Triggers

- A trigger is a statement that is executed automatically by the system as a side effect of a modification to the database.
- To design a trigger mechanism, we must:
 - Specify the conditions under which the trigger is to be executed.
 - Specify the actions to be taken when the trigger executes.
- Triggers introduced to SQL standard in SQL:1999, but supported even earlier using non-standard syntax by most databases.
 - Syntax illustrated here may not work exactly on your database system; check the system manuals

When Not To Use Triggers

- Risk of unintended execution of triggers, for example, when
 - loading data from a backup copy
 - replicating updates at a remote site
 - Trigger execution can be disabled before such actions.
- Other risks with triggers:
 - Error leading to failure of critical transactions that set off the trigger
 - Cascading execution

Recursive Queries

The Power of Recursion

- Recursive queries are powerful and can deal with trees and graphs effectively.
- Recursive views are required to be **monotonic**. Thus they cannot be defined using difference or set aggregates in recursive rules.

OLAP**

Data Analysis and OLAP

- Online Analytical Processing (OLAP)
 - Interactive analysis of data, allowing data to be summarized and viewed in different ways in an online fashion (with negligible delay)

Index Creation

- create table student (ID varchar (5), name varchar (20) not null, dept_name varchar (20), tot_cred numeric (3,0) default 0, primary key (ID))
- create index studentID_index on student(ID)
- Indices are data structures used to speed up access to records with specified values for index attributes
 - e.g. select * from student where ID = '12345'

can be executed by using the index to find the required record, without looking at all records of *student*

More on indices in Chapter 11
